# How do we integrate the *environment* in *engineering* decisions?

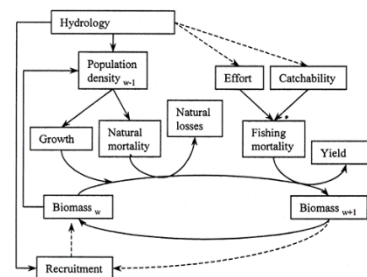

Emission Scenarios

GCM projections as starting point for risk assessment

Hydrologic Model

Ecological Model

DECISION?

# Managing for ecological resilience

Enhance capacity of ecosystem to withstand and recover from disturbance

# Principles of ecological resilience

Rivers are:

1. Dynamic systems – characterized by variation in flows, sediment, nutrients, and salinity. Extremes are often what matter most.
2. Connected systems – longitudinal (upstream/downstream) and lateral (floodplain) connectivity is important for facilitating movement of organisms and enhancing ecosystem productivity.
3. Heterogeneous environments – characterized by structural complexity and gradients from local to catchment scales

# Defining ecological performance criteria

Species– endangered spp, indicator spp, fisheries population targets

Community structure –species composition and diversity

Local-scale habitat heterogeneity – structural habitat complexity

Ecosystem functions – range of variation in flows, sediment transport, nutrients, and salinity

River network connectivity – degree of longitudinal and lateral connectivity/fragmentation

Macro-scale habitat heterogeneity – landscape variation in habitat types

scale

# Stress test sample plots

Engineering performance metric:

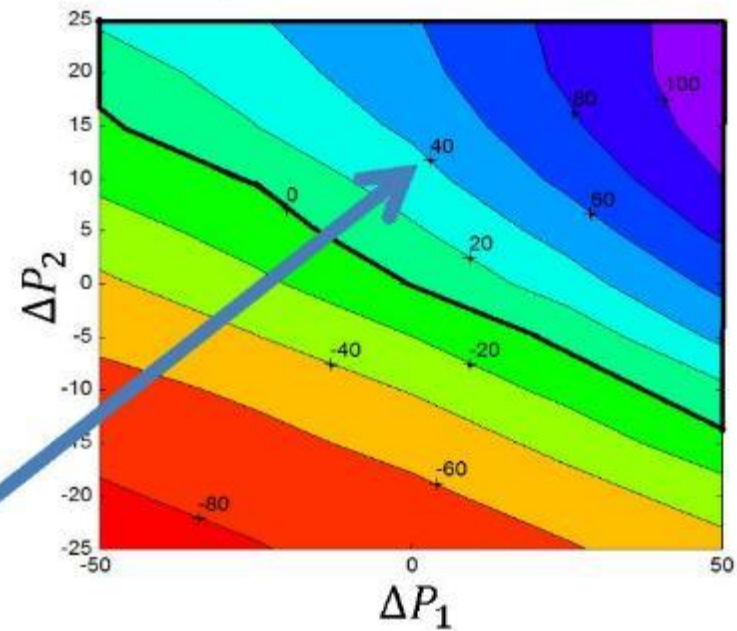

Expected Annual Damage

*Want to minimize -> red is good*

Ecological resilience performance metric:

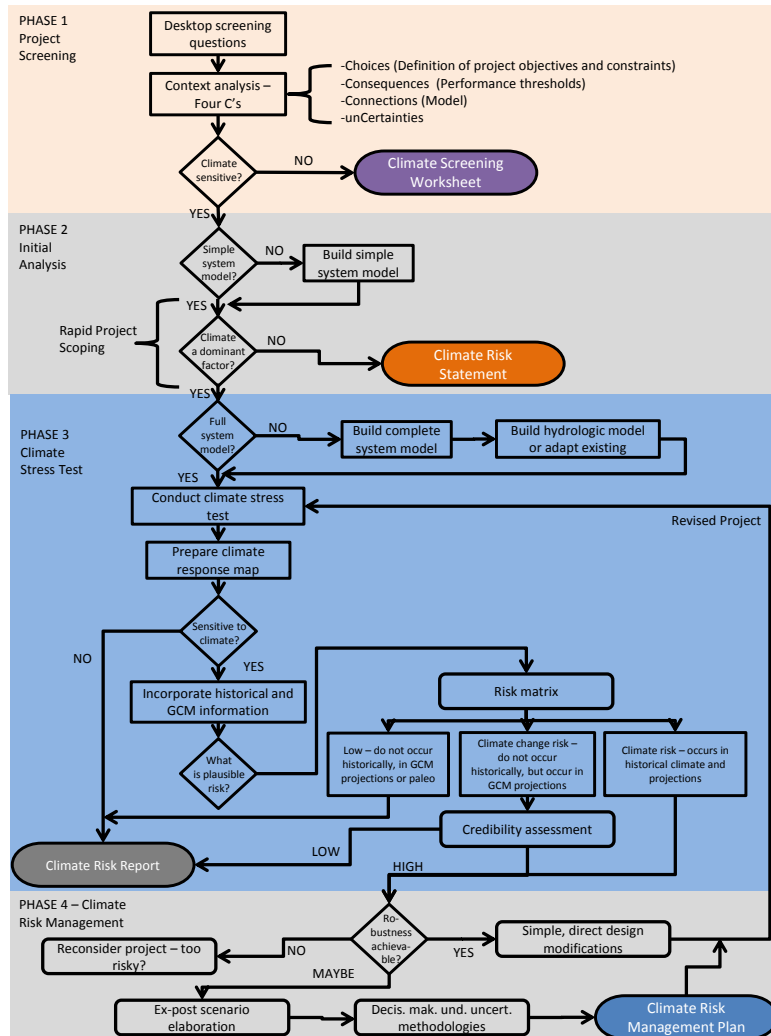

Expected Annual Habitat

*Want to maximize -> red is bad*

**Region of acceptable performance**

# Analysis in the context of stakeholder-driven decision making

# Goal: Maximize area of overlap

Climate space with acceptable performance:

*Inferior Design*

$\Delta P_1$

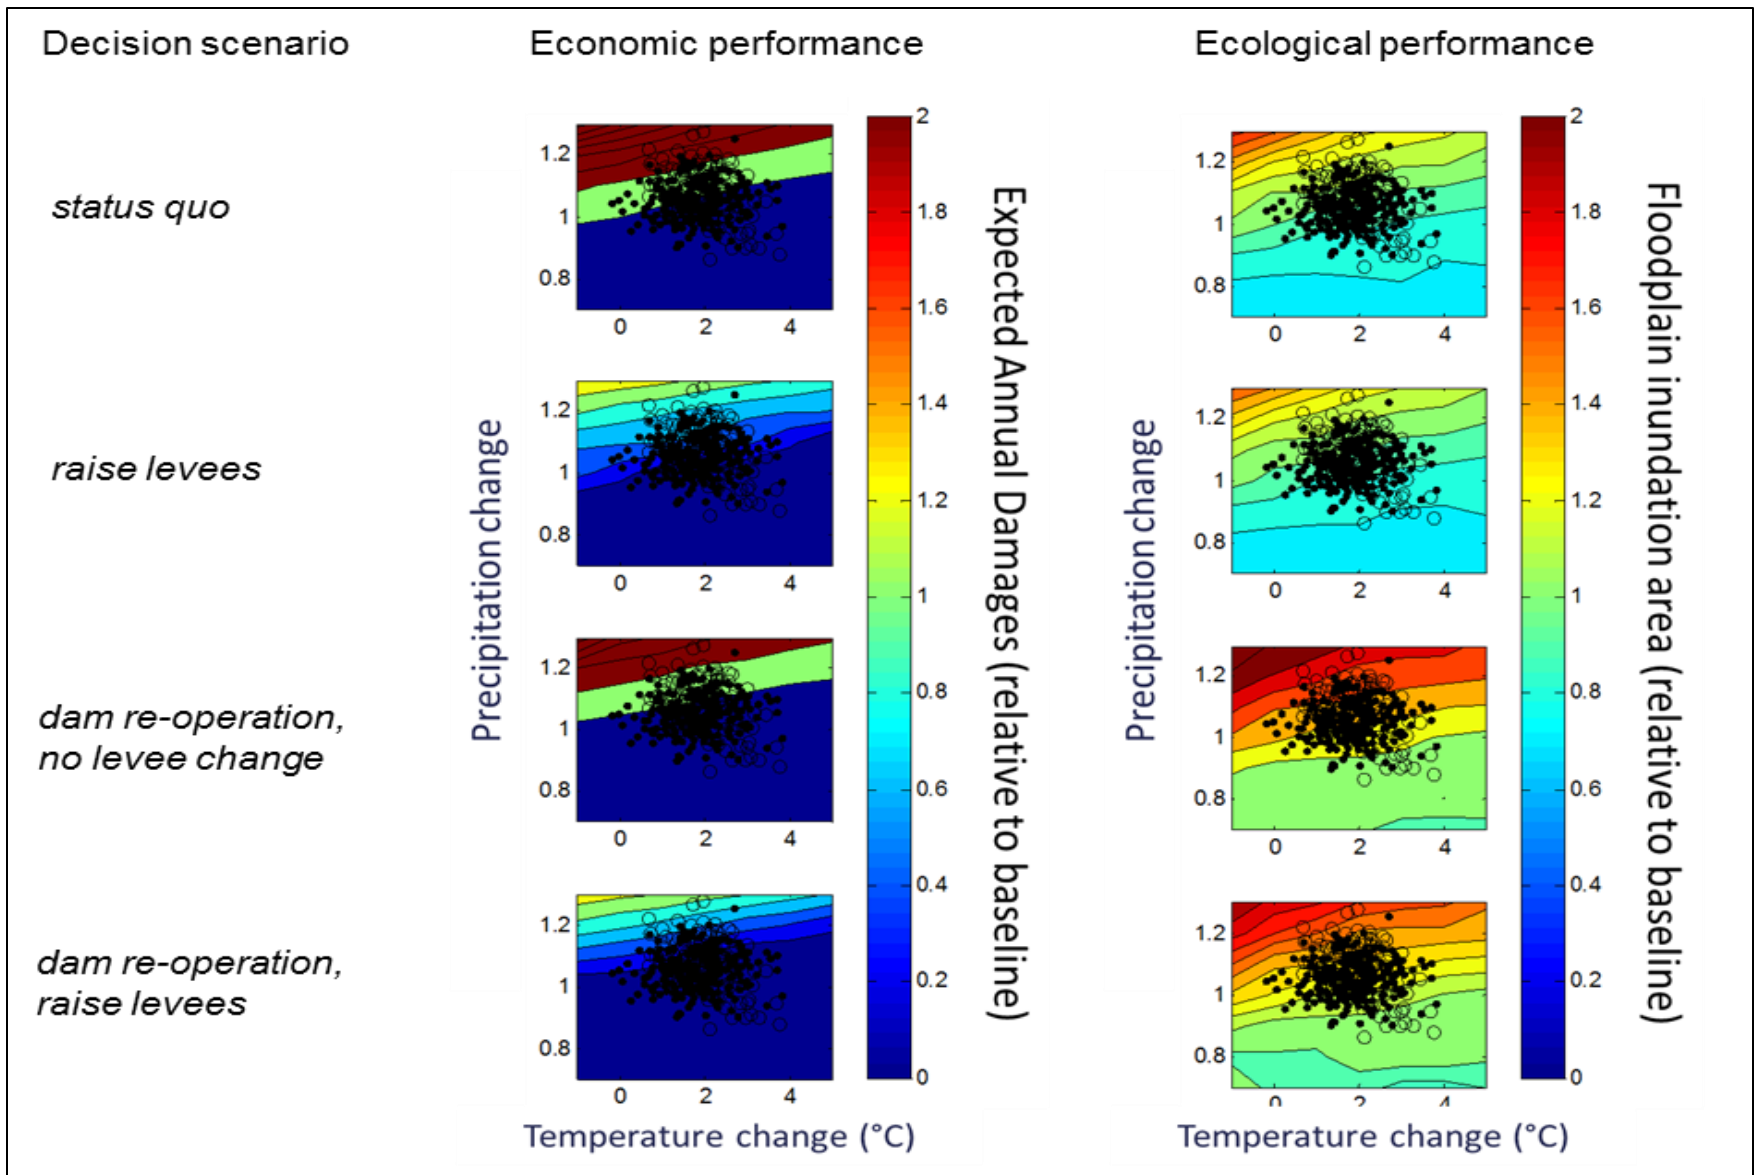

*Superior Design*

← Reduced mutual robustness

Increased mutual robustness →

# Comparing alternatives' climate sensitivity

# Mutual satisficing: Floodplain area and cost

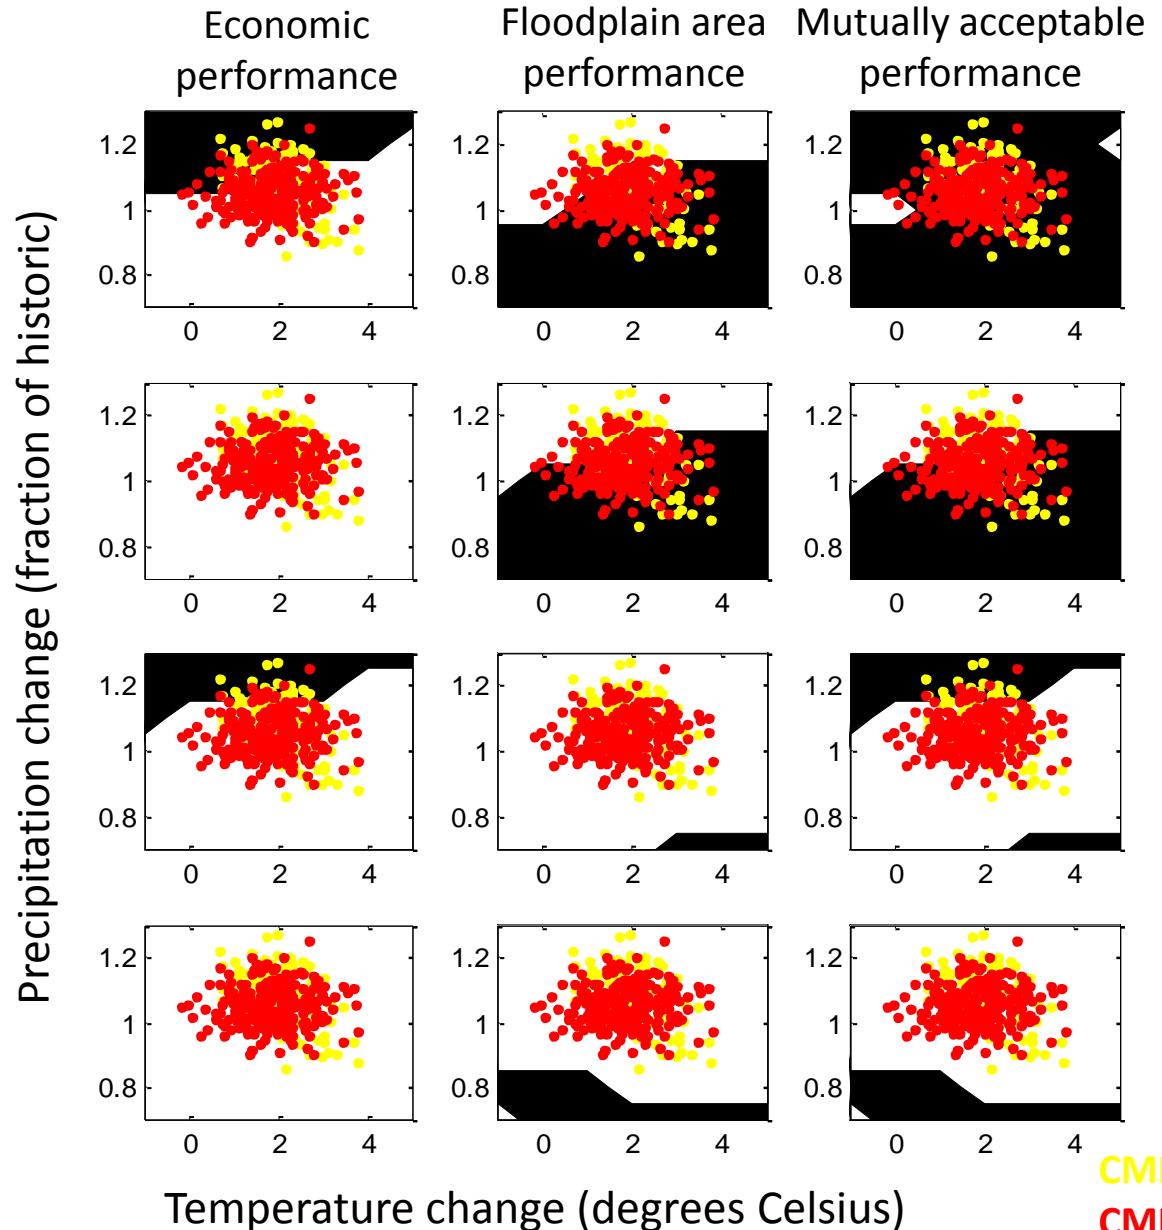

## Adaptation Portfolio

Status quo

Levees raised 9 feet  
No re-operation

No levee change  
Reservoir re-operation

Levees raised 9 feet  
Reservoir re-operation

CMIP3

CMIP5

*Economic threshold = 1.5x historic baseline*

*Area threshold = 1x baseline*

# Is this useful?

- Climate projections inform **(but do not determine)** the decision process
- Decision scaling is **stakeholder-centered and has a strong consensus-based** framework that integrates with technical perspectives, even in highly uncertain environments; *it is perfect for transboundary management*
- Although developed originally for engineers, **eco-engineering decision scaling can easily be implemented for existing approaches** to species- or ecosystem-services oriented approaches
- However, **it is most powerful in low-data environments, when we can compare the three critical “resilience” variables**
- Simultaneously assessing economic and ecological performance of water systems leads to selecting mutually robust adaptation portfolios
- This process can occur early in a project cycle rather than including the environment at the end, as with an EIA, and it allows for direct analysis of tradeoffs at the beginning

Thanks!
