

# Measuring the Value of Data

Canadian System of National Accounts 2023

Delivering insight through data for a better Canada

### Options for measurement:

- 3 approaches that national accounts could potentially use:
  - Market-based: value is determined based on the market price of comparable products on the market
  - Income-based: value is determined by estimating the future cash flows that can be derived from the data
  - Cost-based: value is determined by how much it costs to produce the data

### Options for measurement: market-based approach

- Conceptually preferable method to estimate capital investment, but not always feasible
  - Data may be of most value to the business that collects it and it is never sold
  - ➤ Price depends on the use/user, and the use can depend on what is observed
- If sold, the data has generally undergone transformation and is bundled with other services
  - → 3rd party data is sold after the user's data has been processed (e.g. organizing, cleaning)
- How would repeated sales of same data be measured?

### Options for measurement: income-based approach

- Although income-based valuation is an acceptable method, SNA advises caution
  - riows and the discount factor may be difficult to determine
- Often hard to distinguish cash flows (net of associated costs) uniquely related to the data asset from the cash flows related to other intangibles and services
- Income-based approach is recommended for valuing musical, literary, and photographic works—industries where there is an established system of royalty flows

### Options for measurement: cost-based approach

- Sum of costs approach is the recommended method in absence of observable market transactions and for ownaccount production
- Includes an estimate of labour costs, indirect costs and capital services
  - Labour costs = # of employees \* average compensation \* average time spent
  - Indirect costs include HR resources, electricity, building maintenance, etc.
  - Capital services represents the return on capital assets used in this productive activity

### Sum of costs approach to value data activities

Financial and investment analysts (20%) Social policy researchers, consultants and program officers (30%)

Survey interviewers and statistical clerks (38%)

Data entry clerks (100%)

Data activities

**Economists** and

economic policy

researchers and analysts (40%)

Customer and information services supervisors (50%)

Mathem statistic actuarie

- What occupations are involved in data activities?
- What portion of their tasks relate to data?
- What should be the markup to cover nondirect salary costs?
- > Apply to the wage bill to estimate investment

Mathematicians, statisticians and actuaries (40%)

Example:  Occupational group	'Data' share of production activities	Markup for non- direct-salary costs	Labour compensation	Investment in 'DATA'
			(\$n	nillions)
Financial and investment analysts	20%	53%	7,348	2,249
Customer and information services				
supervisors	50%	53%	668	511

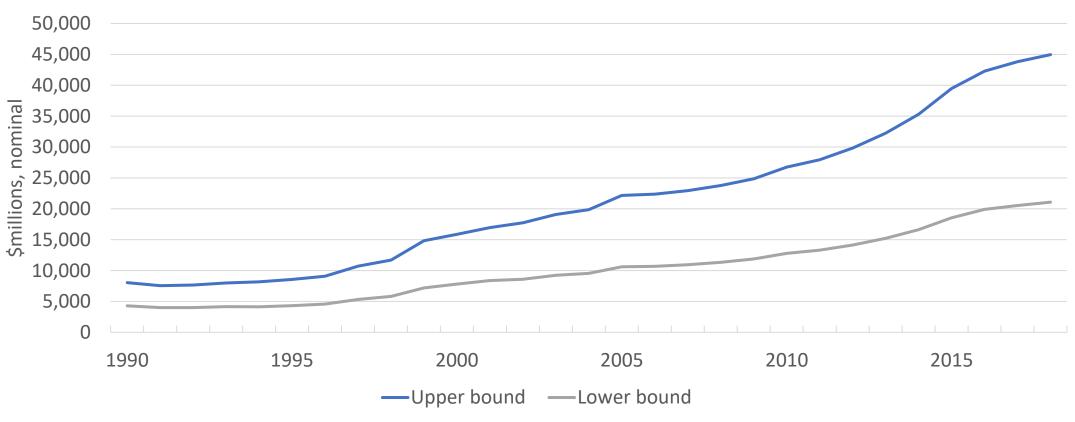

### Investment in data activities

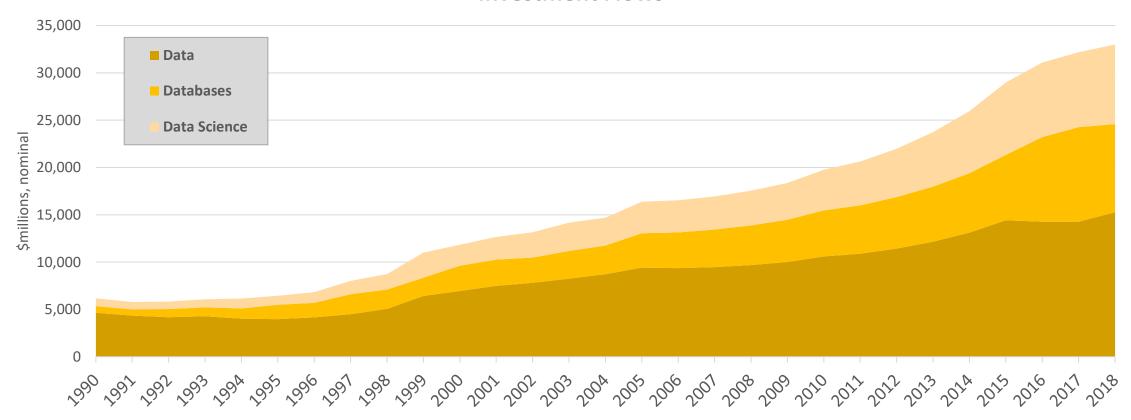

#### **Upper and lower ranges**

# Investment, by type of Data asset

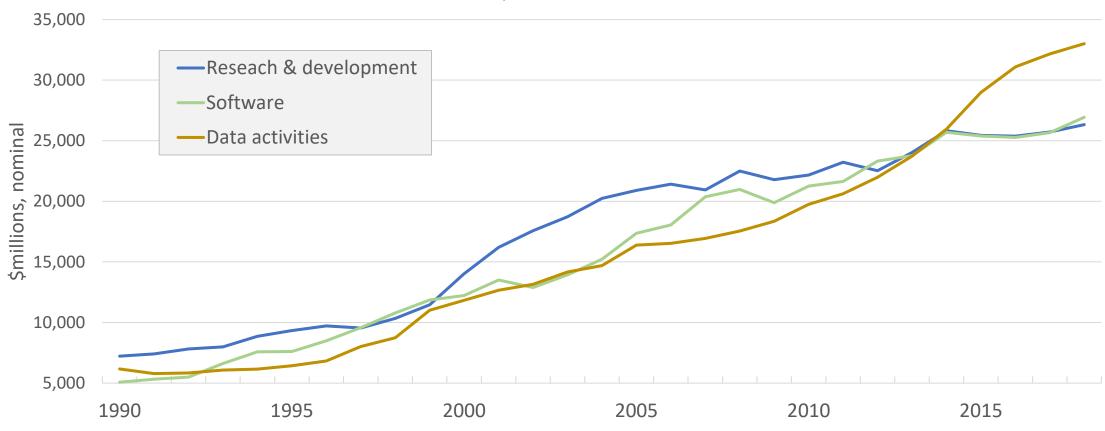

#### **Investment Flows**

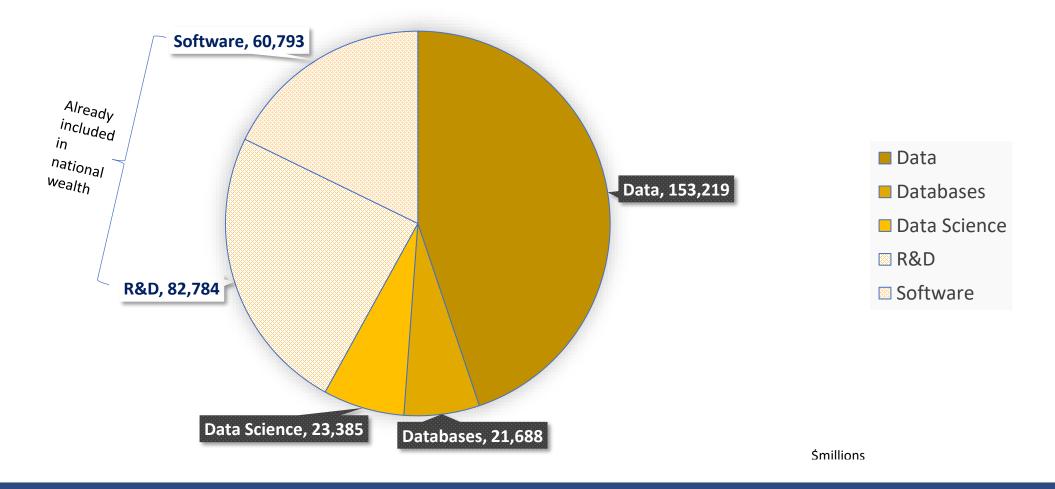

### Investment in intangibles: with data activities

Investment in R&D, software and data activities

### What is the stock of data activities?

### Sum of costs approach: considerations

- Overlap with other IPP production:
  - "it is important to ensure, in using the sum of costs approach to valuating of IPP assets produced on own-account, that the same costs are not included in the valuation of more than one asset"
  - > we know there is some overlap with software
- Choice of occupation and time spent on these activities:
  - >This could be very narrow or very broad
  - ➤ Concrete examples of what is considered Data activities is required
- Mark-up to cover indirect costs and capital services

### Update to the Value of Data Activities release

- Estimated based on the Sum of Costs method
  - Certain occupation types, estimates of time spent
- Previous methodology was ad hoc/arbitrary
  - > which occupations to include and time-use proportions
- Challenges related to estimating occupations and time:
  - ➤ Occupations engaged in data-related tasks are not obvious
  - Tasks are evolving as our economy evolves
  - ➤ Occupations may be involved in more than one stage

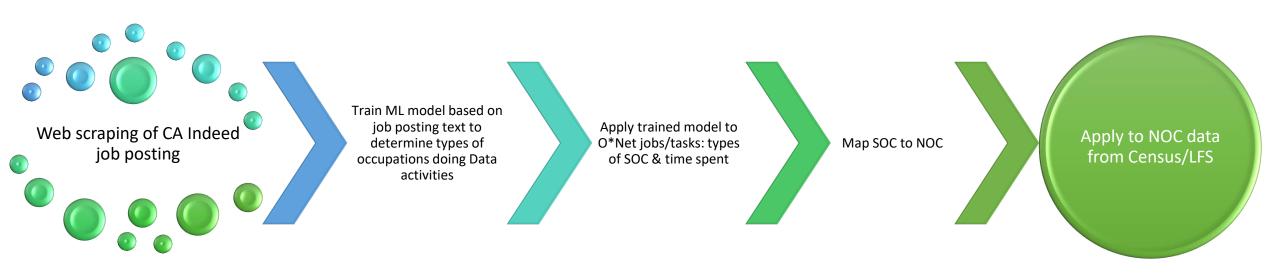

### Update to the Value of Data Activities release, cont.

- Use machine learning to refine the types of occupations and timeuse indeed
  - > Web scraping to obtain jobs listings
  - ➤ Machine learning to identify occupations involved in data activities based on key words
  - Linking those occupations to O\*Net from the BLS that lists job tasks and importance

## Update to the Value of Data Activities release, cont.

\*SOC: US occupational classification

### Update to the Value of Data Activities release

- This will give a selection of occupations that are participating in data activities based on 'real' tasks
- Directly comparable with the US estimates

  Can this method be used for other Sum of costs estimation?
- Considerations with this method:
  - only one job posting site
  - set period of time
  - US listing of occupation tasks/importance
